

Element-wise Selective Smoothed Finite Element Method for **10-node** Tetrahedral Elements in Large Deformation Problems

Yuki ONISHI

Tokyo Institute of Technology, Japan

Motivation

What we want to do:

- Solve **hyper large deformation** analyses accurately and stably.
- Treat complex geometries with **tetrahedral meshes**.
- Consider **nearly incompressible materials** ($\nu \approx 0.5$).
- Support **contact** problems.
- Handle **auto re-meshing**.

Issues

Conventional **tetrahedral (T4/T10)** FE formulations still have issues in accuracy or stability especially in **nearly incompressible** cases.

- 2nd or higher order elements:
 - ✗ Volumetric locking.
Accuracy loss in large strain due to intermediate nodes.
- B-bar method, F-bar method, Selective reduced integration:
 - ✗ Not applicable to tetrahedral element directly.
- F-bar-Patch method:
 - ✗ Difficulty in building good-quality patches.
- u/p mixed (hybrid) method:
(e.g., ABAQUS/Standard **C3D4H** and **C3D10MH**)
 - ✗ Pressure checkerboarding, Early convergence failure etc..
- F-bar type smoothed FEM (F-barES-FEM-T4):
 - ✓ Accurate and stable!

Issues (cont.)

E.g.) Compression of neo-Hookean hyperelastic body with $\nu_{ini} = 0.49$

Pressure

Pressure

of Nodes is almost the same.

1st order hybrid T4 (C3D4H)

- ✓ No volumetric locking
- ✗ Pressure checkerboarding
- ✗ Shear & corner locking

2nd order modified hybrid T10 (C3D10MH)

- ✓ No shear/volumetric locking
- ✗ Early convergence failure
- ✗ Low interpolation accuracy

Issues (cont.)

E.g.) Compression of neo-Hookean hyperelastic body with $\nu_{ini} = 0.49$

Same mesh
as **C3D4H**
case.

Although
F-barES-FEM-T4 is
accurate and stable,
X it cannot be
implemented in
general-purpose
FE software
due to the adoption
of ES-FEM.

F-barES-FEM-T4

- ✓ No shear/volumetric locking
- ✓ No corner locking
- ✓ No pressure checkerboarding

Another approach
adopting **CS-FEM**
with **T10** element
would be effective.

Objective

To propose an accurate and stable CS-FEM-T10, “**SelectiveCS-FEM-T10**”, and to implement it into general-purpose FE software.

Table of Body Contents

- Implementation of SelectiveCS-FEM-T10 into ABAQUS
- Summary

Formulation of SelectiveCS-FEM-T10

Brief Review of Edge-based S-FEM (ES-FEM)

- Calculate $[B]$ at each element as usual.
- Distribute $[B]$ to the connecting **edges** with area weight and build $[^{\text{Edge}}B]$.
- Calculate $F, T, \{f^{\text{int}}\}$ etc. in each **edge** smoothing domain.

As if putting
an integration point
on each edge center

ES-FEM can avoid shear locking.
However,
it cannot be implemented in
ordinary FE codes due to the
strain smoothing across
multiple elements...

1. Subdivision into T4 Subelements

The shape function should not be quadratic in large deformation analyses.

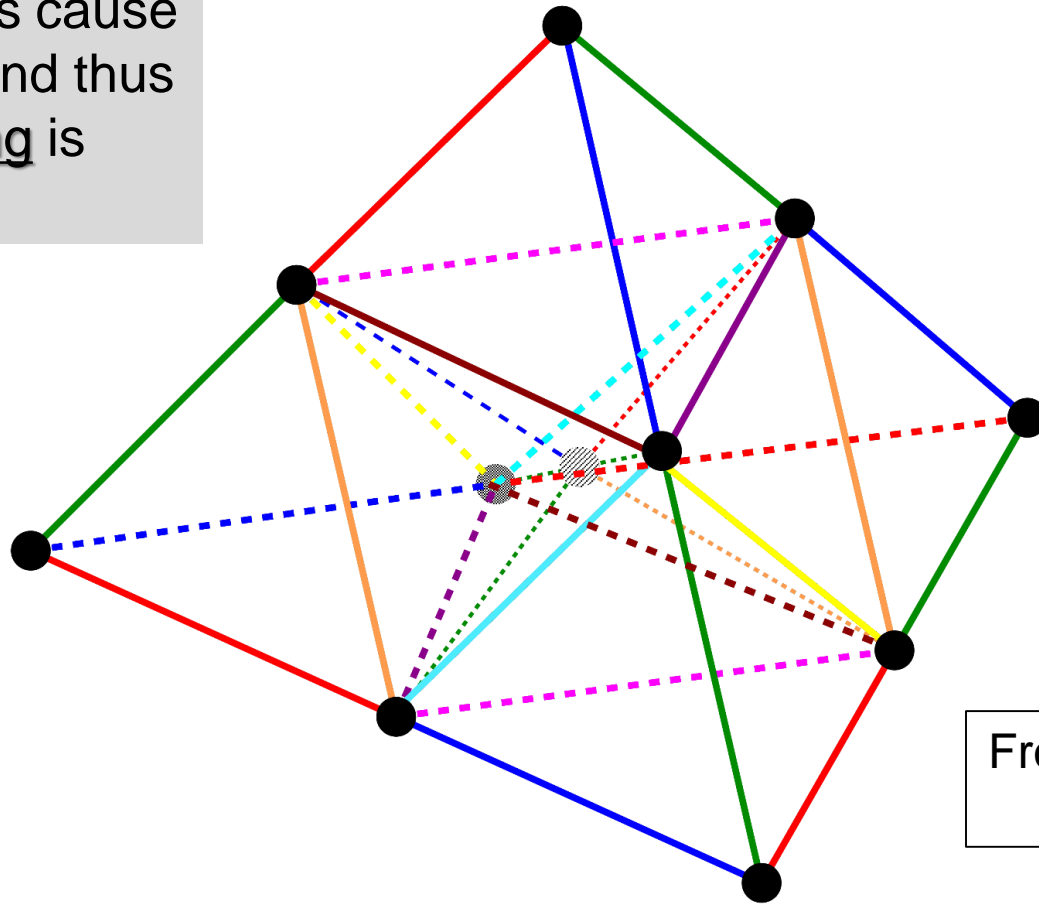

Same as
J.T.Ostien's method.
(IJNME, v107, 2016)

- Put a **dummy node (10)** at the mean location of 6 mid-nodes.
- Subdivide a T10 element into twelve T4 subelements and calculate their B -matrices and strains.

2. Deviatoric Strain Smoothing

T4 subelements cause shear locking and thus strain smoothing is necessary.

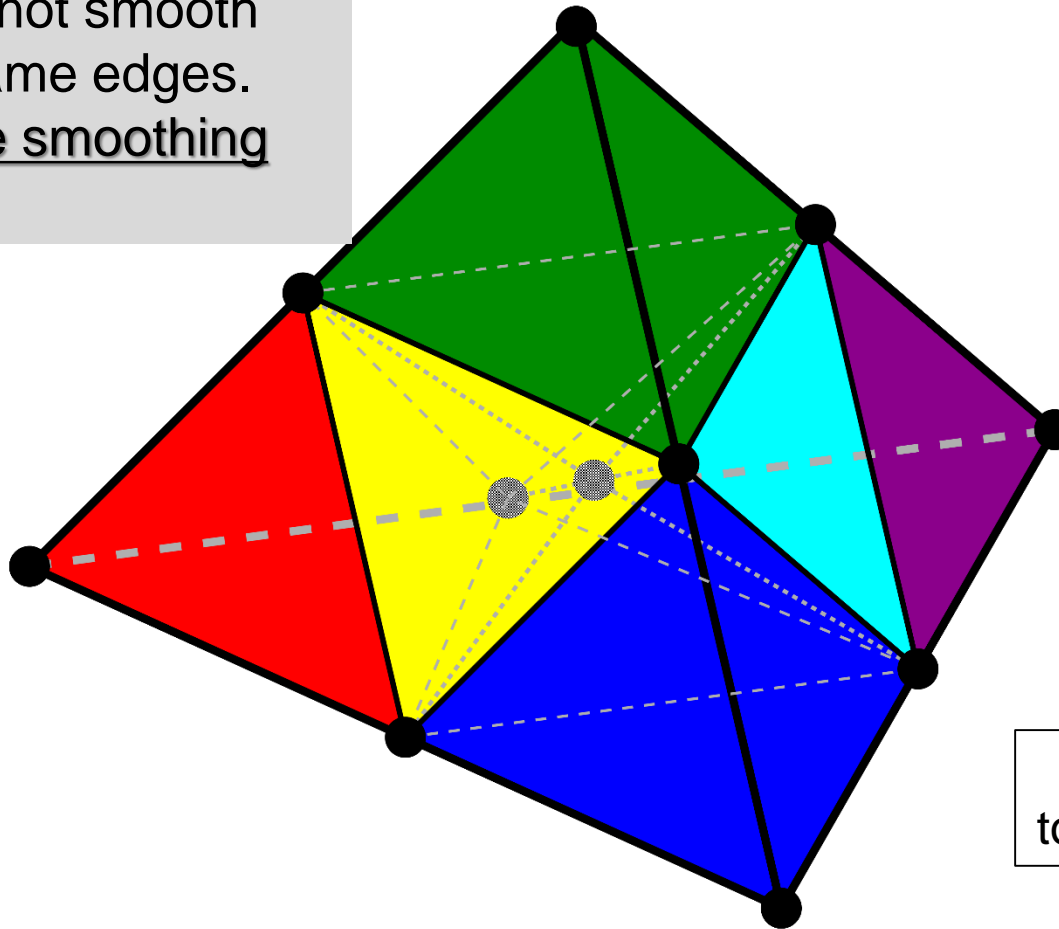

From 12 subelements
to 30 edges

- Perform strain smoothing in the manner of ES-FEM (i.e., average dev. strains of subelements at edges). Then,...

2. Deviatoric Strain Smoothing (cont.)

(cont.)

ES-FEM does not smooth the strain at frame edges. Thus one more smoothing is necessary.

From 30 edges
to 12 subelements

- Perform one more strain smoothing in the reverse direction (i.e., average dev. strains of edges at subelements).

3. Volumetric Strain Smoothing

The spatial order of vol. strain should be lower than that of dev. strain to avoid volumetric locking.

- Treat the mean vol. strain of all subelements as the uniform element vol. strain (i.e., same approach as SRI elements).

Flowchart of SelectiveCS-FEM

Explanation in 2D (6-node triangular element) for simplicity

Demonstration of SelectiveCS-FEM-T10

Barreling of Hyperelastic Cylinder

Outline

- Enforce **axial displacement** on the top face.
- Neo-Hookean body with $\nu_{ini} = 0.49$.
- Compare results with ABAQUS T10 hybrid elements (C3D10H, C3D10MH, C3D10HS) using the same mesh.

Barreling of Hyperelastic Cylinder

Animation of Mises stress (ABAQUS C3D10MH)

Convergence failure at **24%** compression

Unnaturally oscillating distributions are obtained around the rim.

Barreling of Hyperelastic Cylinder

Animation of Mises stress (Selective CS-FEM-T10)

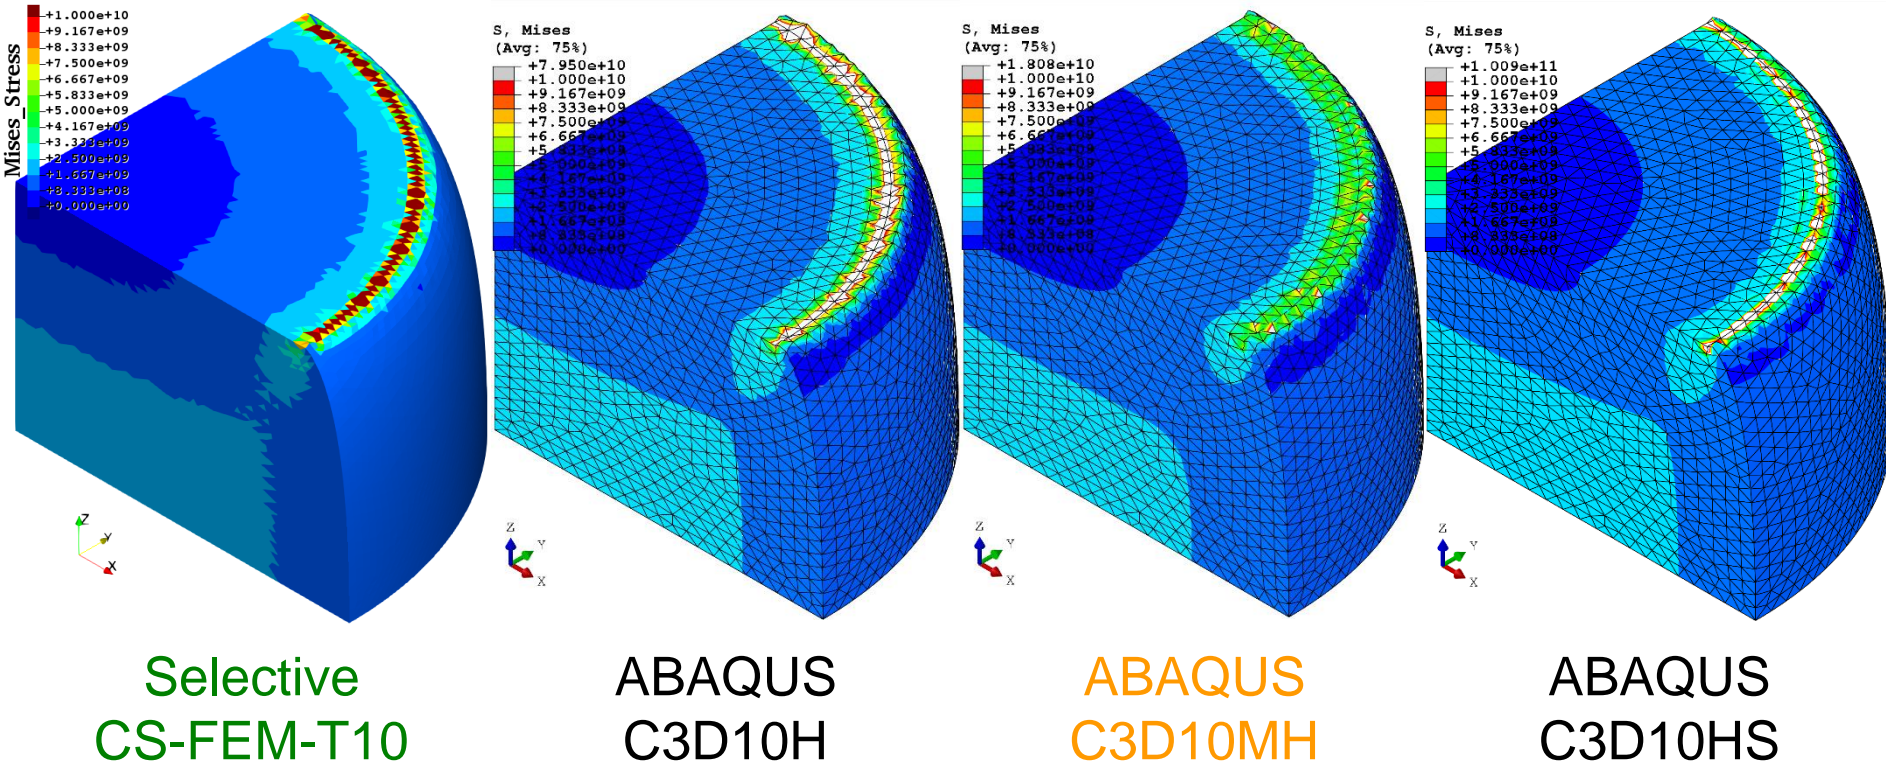

Convergence failure at 47% compression

Smooth distributions are obtained except around the rim.

The present element is more **stable** than ABAQUS C3D10MH

Barreling of Hyperelastic Cylinder

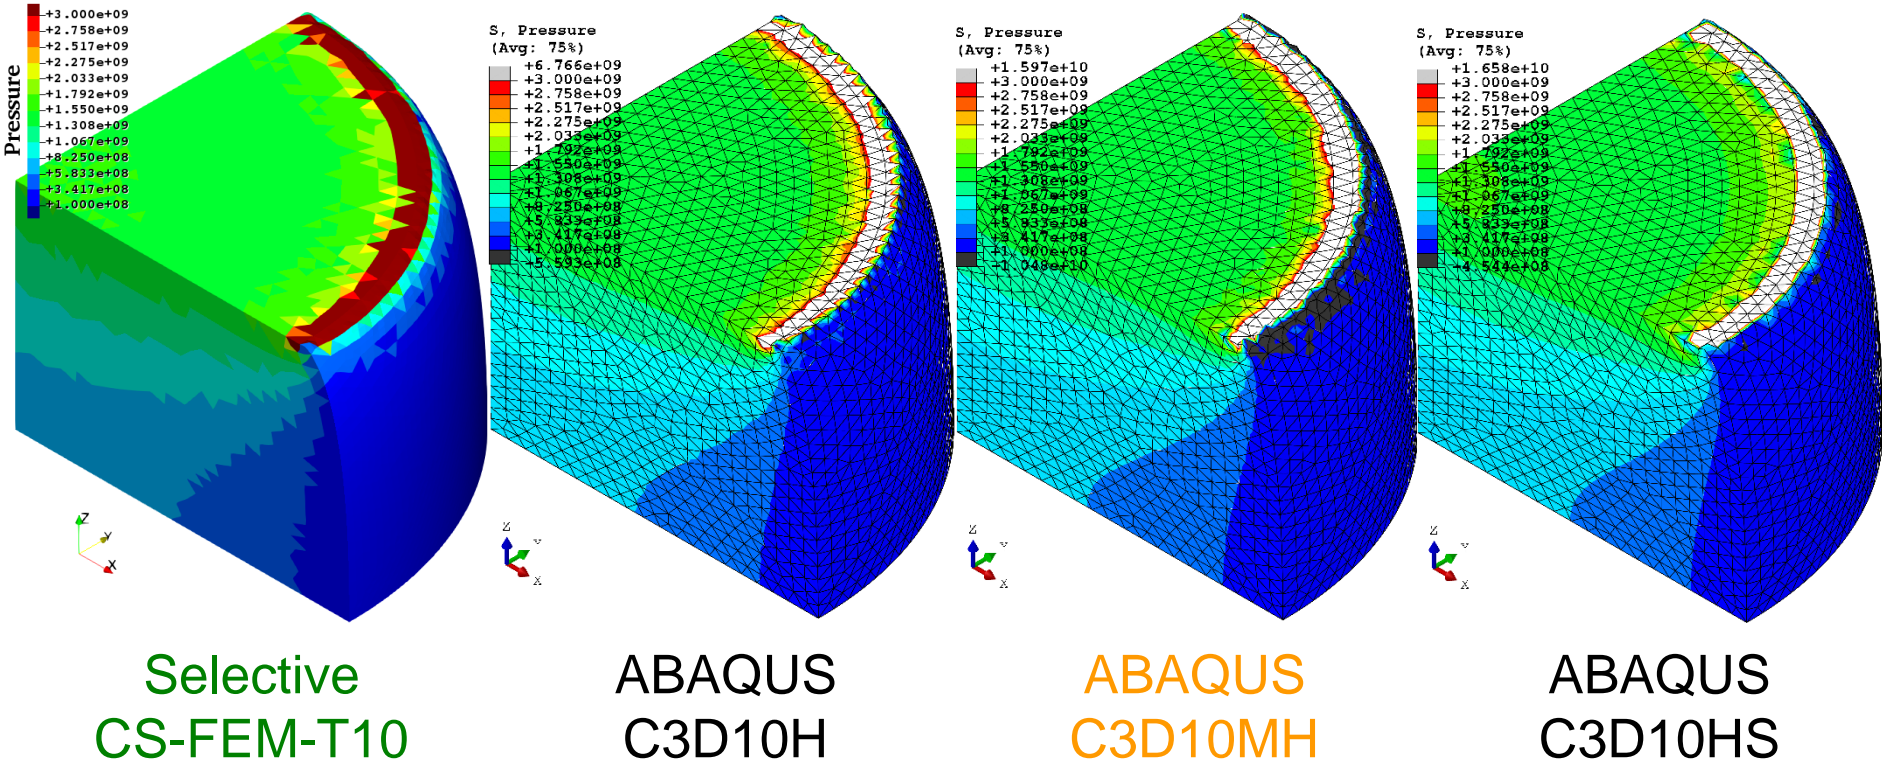

Comparison of Mises stress at 24% comp.

All results are similar to each other except around the rim having stress singularity.

Barreling of Hyperelastic Cylinder

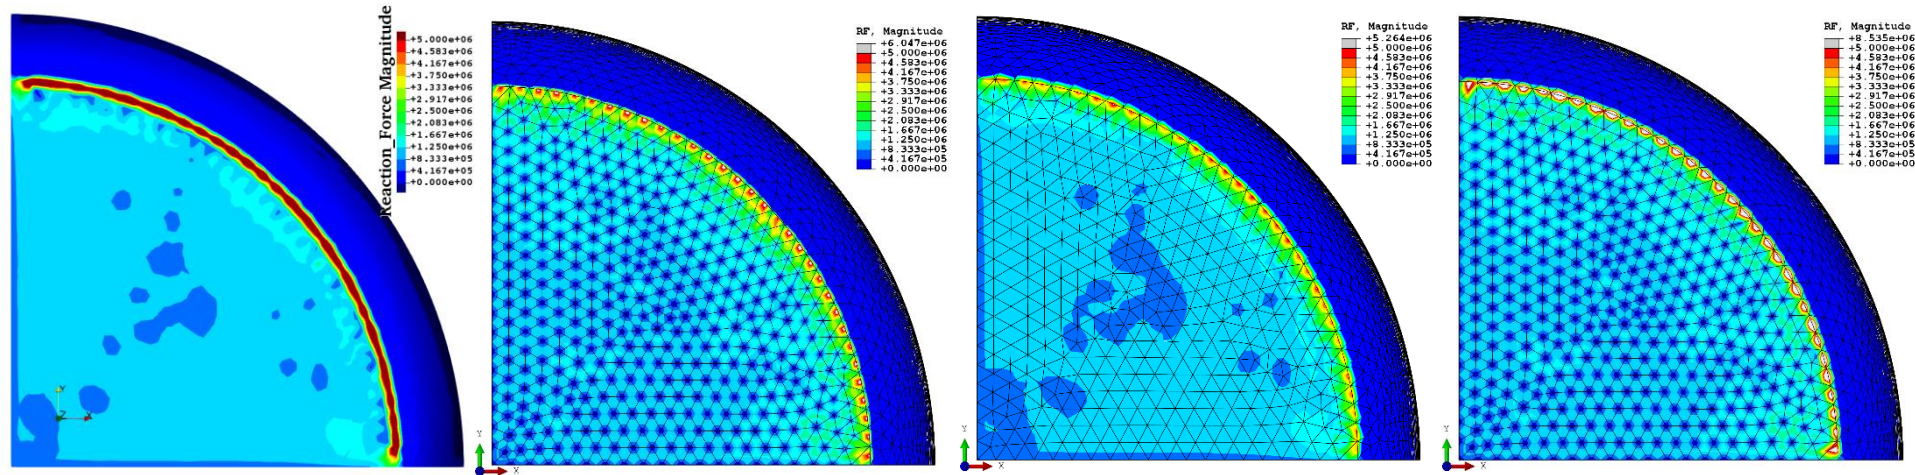

Comparison of pressure at 24% comp.

All results are similar to each other except around the rim having stress singularity.

Barreling of Hyperelastic Cylinder

Comparison of nodal reaction force at 24% comp.

Selective
CS-FEM-T10

ABAQUS
C3D10H

ABAQUS
C3D10MH

ABAQUS
C3D10HS

ABAQUS C3D10H and C3D10HS
suffer from nodal force oscillation.

Barreling of Hyperelastic Cylinder

Comparison of pressure at 47% comp.

of nodes are about 60k in both.

SelectiveCS-FEM-T10

ABAQUS C3D8

Conv. failure at 50% comp.

The present element has competitive accuracy and stability as much as H8-SRI element.

Implementation of SelectiveCS-FEM-T10 into ABAQUS

Brief of ABAQUS UEL

- ABAQUS has functionality of “**u**ser-defined **e**lement” (simply called “**UEL**”).
- UEL is usually written in Fortran77, but in fact it can be written in **Fortran90**.
- Coding a subroutine named “UEL” and compiling it, one can execute ABAQUS using one’s own element:

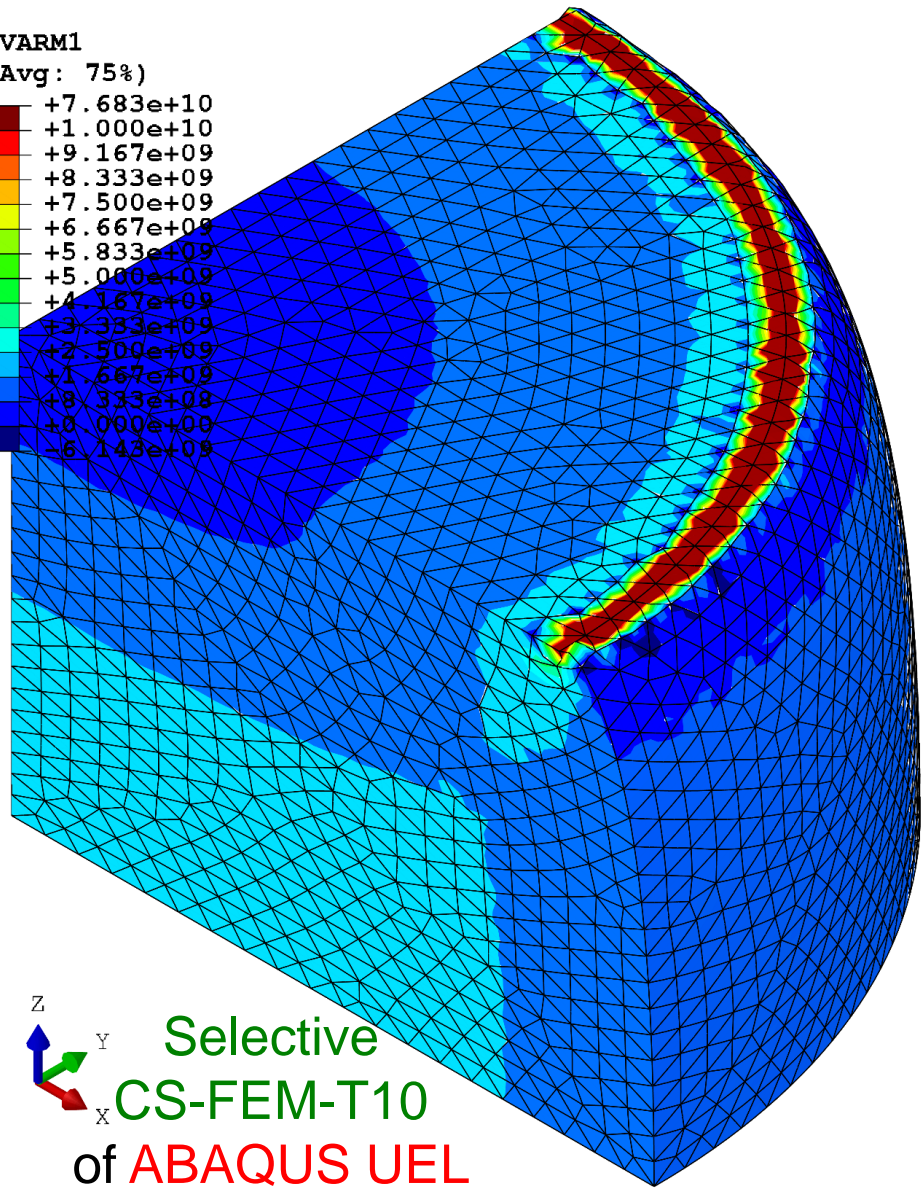

```
% abaqus job=test user=my_uel.o
```
- Analysis results can be visualized on ABAQUS Viewer by defining **overlap elements** with zero stiffness in the “inp” file.

Results of ABAQUS UEL

Comparison of Mises stress (24% comp.)

Selective CS-FEM-T10 of in-house code

A 3D finite element analysis plot showing Mises stress distribution on a curved, shell-like structure, similar to the in-house code plot. The stress is visualized using a color scale from blue to red. The highest stress concentration is visible along the inner edge. A legend on the left lists stress values from +7.683e+10 down to -6.143e+08. A small 3D coordinate system (x, y, z) is shown at the bottom left.

Selective CS-FEM-T10 of ABAQUS UEL

Well agreed with in-house code.

Small difference comes from the difference of mapping calculation.

calculation.

Issues in ABAQUS UEL

- We have to define the overlap elements
 - to visualize the results with ABAQUS Viewer.
 - to define element-based surface for pressure loading, contact pair definition etc..
- The overlap elements cause convergence failure in large deformation analysis.
i.e., the cylinder barreling analysis stops at 24% compression when the overset elements are defined.

Native implementation is essential for the full use of SelectiveCS-FEM-T10, unfortunately...

Summary

Summary of SelectiveCS-FEM-T10

Benefits

- ✓ Locking-free.
- ✓ No pressure checkerboarding.
- ✓ No nodal force oscillation.
- ✓ No increase in DOF.
- ✓ Long lasting in large deformation.
- ✓ Nearly same CPU cost as the standard T10 elements.

Drawbacks

- ✗ No longer a T4 formulation.

Take-home message

Please consider implementing SelectiveCS-FEM-T10 to your in-house code. It's very easy!!

Thank you for your kind attention!
